Cables, cable assemblies and connectors –
Introduction to electromagnetic (EMC)
screening measurements

Câbles, cordons et connecteurs –
Introduction aux mesures de blindage électromagnétique
Numbering

As from 1 January 1997 all IEC publications are issued with a designation in the 60000 series.

Consolidated publications

Consolidated versions of some IEC publications including amendments are available. For example, edition numbers 1.0, 1.1 and 1.2 refer, respectively, to the base publication, the base publication incorporating amendment 1 and the base publication incorporating amendments 1 and 2.

Validity of this publication

The technical content of IEC publications is kept under constant review by the IEC, thus ensuring that the content reflects current technology.

Information relating to the date of the reconfirmation of the publication is available in the IEC catalogue.

Information on the subjects under consideration and work in progress undertaken by the technical committee which has prepared this publication, as well as the list of publications issued, is to be found at the following IEC sources:

- IEC web site*
- Catalogue of IEC publications
  Published yearly with regular updates
  (On-line catalogue)*
- IEC Bulletin
  Available both at the IEC web site* and as a printed periodical

Terminology, graphical and letter symbols

For general terminology, readers are referred to IEC 60050: International Electrotechnical Vocabulary (IEV).

For graphical symbols, and letter symbols and signs approved by the IEC for general use, readers are referred to publications IEC 60027: Letter symbols to be used in electrical technology, IEC 60417: Graphical symbols for use on equipment, Index, survey and compilation of the single sheets and IEC 60617: Graphical symbols for diagrams.

* See web site address on title page.

FOREWORD

1) The IEC (International Electrotechnical Commission) is a worldwide organization for standardization comprising all national electrotechnical committees (IEC National Committees). The object of the IEC is to promote international co-operation on all questions concerning standardization in the electrical and electronic fields. To this end and in addition to other activities, the IEC publishes International Standards. Their preparation is entrusted to technical committees; any IEC National Committee interested in the subject dealt with may participate in this preparatory work. International, governmental and non-governmental organizations liaising with the IEC also participate in this preparation. The IEC collaborates closely with the International Organization for Standardization (ISO) in accordance with conditions determined by agreement between the two organizations.

2) The formal decisions or agreements of the IEC on technical matters express, as nearly as possible, an international consensus of opinion on the relevant subjects since each technical committee has representation from all interested National Committees.

3) The documents produced have the form of recommendations for international use and are published in the form of standards, technical reports or guides and they are accepted by the National Committees in that sense.

4) In order to promote international unification, IEC National Committees undertake to apply IEC International Standards transparently to the maximum extent possible in their national and regional standards. Any divergence between the IEC Standard and the corresponding national or regional standard shall be clearly indicated in the latter.

5) The IEC provides no marking procedure to indicate its approval and cannot be rendered responsible for any equipment declared to be in conformity with one of its standards.

6) Attention is drawn to the possibility that some of the elements of this International Standard may be the subject of patent rights. The IEC shall not be held responsible for identifying any or all such patent rights.

The main task of IEC technical committees is to prepare International Standards. In exceptional circumstances, a technical committee may propose the publication of a technical report of one of the following types:

- type 1, when the required support cannot be obtained for the publication of an International Standard, despite repeated efforts;
- type 2, when the subject is still under technical development or where, for any other reason, there is the future but not immediate possibility of an agreement on an International Standard;
- type 3, when a technical committee has collected data of a different kind from that which is normally published as an International Standard, for example “state of the art”.

Technical reports of types 1 and 2 are subject to review within three years of publication to decide whether they can be transformed into International Standards. Technical reports of type 3 do not necessarily have to be reviewed until the data they provide are considered to be no longer valid or useful.

IEC 61917 which is a technical report type 3 has been prepared by subcommittee 46A: Coaxial cables, of IEC technical committee 46: Cables, wires, waveguides, r.f. connectors, and accessories for communication and signalling.
The text of this technical report is based on the following documents:

CABLES, CABLE ASSEMBLIES AND CONNECTORS –
INTRODUCTION TO ELECTROMAGNETIC (EMC)
SCREENING MEASUREMENTS

1 Scope and object

Screening (or shielding) is one basic way of achieving electromagnetic compatibility (EMC). However, a confusingly large number of methods and concepts is available to test for the screening quality of cables and related components, and for defining their quality. This technical report gives a brief introduction to basic concepts and terms trying to reveal the common features of apparently different test methods. It should assist in correct interpretation of test data, and in the better understanding of screening (or shielding) and related specifications and standards.

2 Reference documents

IEC 60096-1:1986, Radio-frequency cables – Part 1: General requirements and measuring methods
Amendment 2 (1993)

Amendment 1 (1990)

IEC 60096-4-1:1990, Radio-frequency cables – Part 4: Specification for superscreened cables – Section 1: General requirements and test methods

IEC 60169-1:1987, Radio-frequency connectors – Part 1: General requirements and measuring methods

IEC 61726:1995, Cable assemblies, cables, connectors and passive microwave components – Screening attenuation measurement by the reverberation chamber method

3 Electromagnetic phenomena

It is assumed that if an electromagnetic field is incident on a screened cable, there is only weak coupling between the external field and that inside, and that the cable diameter is very small compared with both the cable length and the wavelength of the incident field. The superposition of the external incident field and the field scattered by the cable yields the total electromagnetic field \( E_t, H_t \), in figure 1). The total field at the screen’s surface may be considered as the source of the coupling: electric field penetrates through apertures by electric or capacitive coupling; also magnetic fields penetrate through apertures by inductive or magnetic coupling.

Additionally, the induced current in the screen results in conductive or resistive coupling.
\[ (E_1, H_1) = (E_s, H_s) + (E_i, H_i) \] (1)
\[ J = n \cdot H_i \] (2)
\[ \sigma = n \cdot E_{\text{ref}_{1}} \] (3)

\( n \): unit vector normal to surface

Figure 1 – Incident \((i)\), scattered \((s)\) and resulting total electromagnetic fields \((E_t, H_t)\) with induced surface current- and surface charge-densities \(J\) (A/m) and \(\sigma\) (C/m²).

As the field at the surface of the screen is directly related to density of surface current and surface charge, the coupling may be assigned either to the total field \((E_t, H_t)\) or to the surface current- and charge- densities \((J\) and \(\sigma\)). Consequently, we may simulate the coupling into the cable by reproducing through any means the surface currents and charges on the screen. Because we assume a cable of a small diameter, we may neglect higher modes and can use an additional coaxial conductor as our injection structure, as shown in figure 2.

Concept of a triaxial set-up

1) outer circuit, formed by injection cylinder and screen, characteristic impedance \(Z_1\),

2) inner circuit, formed by a screen, and centre conductor, characteristic impedance \(Z_2\); screening at the ends not shown.

Figure 2 – Defining and measuring screening parameters – A triaxial set-up

Observe the conditions \(Z_{1f}, Z_{2n}, Z_{2f}\) and \(\lambda\) in figure 3a and figure 3b.

NOTE 1 – \(D_i << l\).

NOTE 2 – Both ends of circuit (2) must be well screened.
4 The intrinsic screening parameters of short cables

The intrinsic parameters refer to an infinitesimal length of cable, like the inductance or capacitance per unit length of transmission lines. Assuming electrically short cables, with \( l << \lambda \) which will always apply at low frequencies, the intrinsic screening parameters are defined and can be measured as follows:

4.1 Surface transfer impedance, \( Z_T \)

As shown in figure 2 and figure 3a (where \( Z_{1f} \) and \( Z_{2f} \) are zero):

\[
Z_{UI} l T = \frac{21}{(U_1 \cdot l)} \ (\Omega/\text{m})
\]

The dependence of \( Z_T \) on frequency is not simple and is often shown by plotting \( \log Z_T \) against \( \log \) frequency. Note that the phase of \( Z_T \) may have any value, depending on braid construction and frequency range.

NOTE – In circuit 2 of figure 3a the voltmeter and short circuit can be interchanged.

4.2 Capacitive coupling admittance, \( Y_c \)

As shown in figure 2 and figure 3b (where \( Z_{1f} \) and \( Z_{2f} \) are open circuit):

\[
Y_C = j\omega C_T = \frac{I_2}{(U_1 \cdot l)} \ (\text{mho/\text{m})}
\]

The through capacitance (\( C_T \)) is a real capacitance and has usually a constant value up to 1 GHz and higher (with aperture \( a << \lambda \)).

While \( Z_T \) is independent of the characteristics of the coaxial circuits, \( C_T \) is dependent on those characteristics. There are two ways of overcoming this dependence:

a) The normalized through elastance \( K_T \) derived from \( C_T \) is independent of the size of the outer coaxial circuit, but it depends on its permittivity:

\[
K_T = \frac{C_T}{(C_1 \cdot C_2)} \ (\text{m/F}) \quad K_T \sim 1/(\varepsilon_{r1} + \varepsilon_{r2})
\]

where \( C_1 \) and \( C_2 \) are the capacitance per unit length of the two coaxial circuits.

b) The capacitive coupling impedance \( Z_F \) again derived from \( C_T \) is also independent of the size of the outer coaxial circuit and, for practical values of \( \varepsilon_{r1}, \) is only slightly dependent on its permittivity:

\[
Z_F = Z_1Z_2Y_C = Z_1Z_2 j\omega C_T \ (\Omega/\text{m}) \quad Z_F \sim \sqrt{(\varepsilon_{r1} \cdot \varepsilon_{r2})}/(\varepsilon_{r1} + \varepsilon_{r2})
\]

Compared with \( Z_T, \) \( Z_F \) is usually negligible, except for open weave braids. It may, however, be significant when \( Z_{2n} \) and \( Z_{2f} >> Z_2 \) (audio circuits).
Figure 3a – Equivalent circuit for the definition and possible testing of $Z$

$Z_{1f} = 0$

$Z_{2f} = 0$

$l << \lambda$

Figure 3b – Equivalent circuit for the definition and possible testing of $Y_c = j \omega C_T$

$Z_{1} = \infty$

$Z_{2} = \infty$

$l << \lambda$

Figure 3c – Definition of electrical quantities in a set-up that is matched at all ends

NOTE – $Z_1$ and $C_T$ are distributed (not correctly shown here). The loads $Z_2$ at the ends may represent matched receivers.

Figure 3 – Defining and measuring screen parameters – Equivalent circuits
4.3 Injecting with arbitrary cross-sections

A coaxial outer circuit has been assumed so far in this report, but it is not essential because of the invariance of $Z_T$ and $Z_F$. Using a wire in place of the outer cylinder, the injection circuit becomes two-wire with the return via the screen of the cable under test. Obviously the charge and current distribution become non-uniform, but the results are equivalent to coaxial injection, especially if two injection lines are used opposite to each other, and may be justified for worst-case testing. Note that the IEC line injection test uses a wire.

4.4 Reciprocity and symmetry

Assuming linear shield materials, the measured $Z_T$ and $Z_F$ values will not change when interchanging injection (1) and measuring (2) circuits. Each of the two conductors of the two-line circuit can be interchanged, but in practice the set-up will have to take into account possible ground loops and coupling to the environment.

4.5 Arbitrary load conditions

When the circuit ends of figure 3a and figure 3b are not ideally short or open circuit, $Z_T$ and $Z_F$ will act simultaneously. The superposition is noticeable in the low frequency coupling of the matched circuits (figure 3c and table 1).

5 Long cables – coupled transmission lines

The coupling over the whole length of the cable is obtained by summing up (integrating) the infinitesimal coupling contributions along the cable while observing the correct phase. It is expedient to make the following assumptions and conventions:

- matched circuits considered with the voltage waves $U_1$, $U_{2n}$, $U_{2f}$, see figure 3c,
- representation of the coupling, using the normalized wave amplitudes $U / \sqrt{\text{Watt}}$.

instead of voltage waves. i.e. the coupling transfer function, in the following denoted by "coupling function", will be defined as

$$T_n = \frac{U_{2n}}{U_1 / \sqrt{Z_2}} \quad T_f = \frac{U_{2f}}{U_1 / \sqrt{Z_1}}$$

(10) (11)

NOTE 1 – $|T|^2$ is the ratio of the power waves travelling in circuits (2) and (1). Due to reciprocity and assuming linear screen (shield) materials, $T$ is reciprocal, i.e. invariant with respect to the interchange of injection and measuring circuits (1) and (2).

NOTE 2 – The quantity $|1/T|^2$, or in logarithmic quantities

$$A_S = -20 \log_{10} |T|$$

(12)

may be considered as the "screening attenuation" of the cable, specific to the set-up.

Performing the straight forward calculations of coupled transmission line theory, the coupling function $T$, given in table 1, is obtained. The term $S \{lf \}$ is the "summing function" $S$, being dependent on $l$ and $f$. (The wavy bracket just indicates that the product $l \cdot f$ is the argument of the function $S$ and not a factor to $S$). $S$ represents the phase effect, when summing up the infinitesimal couplings along the line, and is:

$$S_n \{lf \} = \frac{\sin \beta l \pm 2}{\beta l \pm 2} \exp \left\{ -j \frac{\beta l \pm 2}{2} \right\}$$

(13)
with

\[ \beta l_{\pm} = (\beta_2 \pm \beta_1) \cdot l = 2\pi l f \left\{ 1/ v_2 \pm 1/ v_1 \right\} = 2\pi l f \left( \sqrt{e_{r_2}} \pm \sqrt{e_{r_1}} \right) / c \] \tag{14a} \tag{14b} \tag{14c}

subscript \( \pm \) refers to near/far end respectively
\( + \) refers to both near/far ends

Note that weak coupling, i.e. \( T \ll 1 \), has been assumed. This case, including losses, is given in [20 Halme, Szentkuti]*.

NOTE – The equation (15) and representation in table 1 visualizes the contributions of the different parameters to the coupling function \( T \):

\[ T_n = (Z_F \pm Z_r) \cdot \frac{1}{\sqrt{Z_1 \cdot Z_2}} \cdot \frac{l}{2} \cdot S_n \left\{ l \cdot f, e_{r_1}, e_{r_2} \right\} \] \tag{15}

Note especially the following points:

a) There may be a directional effect \( (T_n \neq T_f ) \) in the whole frequency range if \( Z_F \) is not negligible. (But \( Z_F \) is usually negligible except with loose, single braid shields.)

b) Up to a constant factor, \( T \) is the quantity directly measured in a set-up.

c) For low frequencies, i.e. for short cables \( (l << \lambda) \), the trivial coupling formula is obtained that is directly proportional to \( l \):

\[ T_n = (Z_F \pm Z_r) \cdot \frac{1}{Z_{12}} \cdot \frac{l}{2}, \text{ with } Z_{12} = \sqrt{Z_1 \cdot Z_2} \] \tag{16a} \tag{16b}

d) The summing function \( S\{l \cdot f\} \) is presented in figure 4. Note also that:

e) \( S\{l \cdot f\} \) has a \( \sin(x)/x \) behaviour. A cut-off point may be defined as \( (l \cdot f)_C \):

\[ (l \cdot f)_C = \frac{e}{\pi \sqrt{e_{r_1} \pm e_{r_2}}} \] \tag{17}

f) The exact envelope of \( S\{l \cdot f\} \) is

\[ \text{Env} \left\{ S_n \{l \cdot f\} \right\} = \frac{1}{\sqrt{1 + \frac{(l \cdot f)^2}{(l \cdot f)_C^2}}} \] \tag{18}

* Numbers in square brackets refer to the bibliography (see annex B).
### Table 1 – The coupling transfer function $T$ (coupling function)$^{1)}$

<table>
<thead>
<tr>
<th>Set-up parameters $^{2)}$</th>

</thead>
<tbody>
<tr>
<td>$T_n = (Z_F \pm Z_T) \cdot \frac{1}{\sqrt{Z_1 \cdot Z_2}} \cdot \frac{l}{2} \cdot S_n { l \cdot f, \varepsilon_{r1}, \varepsilon_{r2} }$</td>
<td></td>
</tr>
</tbody>
</table>

**Intrinsic** screen parameters

**Cable parameters $^{2)}$** (Z₂, l), $\varepsilon_{r2}$

"Low-frequency coupling", short cables $^{3)}$

"HF-effect", cut-off $(l \cdot f)_C$

**Length + frequency effect**

---

1) $T^2$ is the power coupling from circuit (1) to circuit (2).

The stacked subscripts $^f$ are associated to the stacked operation symbols $\pm$ in the obvious way: upper subscript $\rightarrow$ upper operation, lower subscript $\rightarrow$ lower operation.

2) $\varepsilon_{r1}$ and $\varepsilon_{r2}$ contained in $S$ as parameters.

3) for $l \ll \lambda: S\{l \cdot f\} \rightarrow 1$.

---

**g)** The first minimum (zero) of $S\{l \cdot f\}$ occurs at

$$ (l \cdot f)_{\text{min}} = \pi (l \cdot f)_C. \quad (19) $$

**h)** As seen from equations (13) and (18), below the cut-off points $(l \cdot f)_{cn}$ is $S\{l \cdot f\} = 1$ and above them it starts to oscillate and its envelope drops asymptotically 20 dB/decade,

$$ \text{Env} \left| \frac{S_n \{l \cdot f\}}{f} \right| \approx \frac{(l \cdot f)_{cn}}{(l \cdot f)} \quad (20) $$
i) $S$ is symmetrical in $l$ and $f$, i.e. $l$ and $f$ are interchangeable. For a fixed length a cut-off frequency $f_c$ and vice versa, for a fixed frequency a cut-off length $l_c$ may be defined. Substituting $c/\lambda_o$ for $f$, we obtain the cut-off length as

$$l_{c_i} = \frac{\lambda_o}{\pi \sqrt{|\epsilon_r| \pm |\epsilon_r|}}$$

(21)

j) The effect of $S$ in the frequency range ($l = \text{constant}$) is illustrated in figure 5. The coupling function is proportional to $Z_T$, only if $f < f_c$. Note also the typical values indicated for $f_c$.

k) The minima and maxima of $S$ are not resonances, they are due to cancelling and additive effects of the coupling along the line.

l) The far end cut-off frequency is significantly influenced by the permittivity of the outer system ($\epsilon_r$). Selecting $\epsilon_{r1} \rightarrow \epsilon_{r2}$ we obtain $(l \cdot f)_C \rightarrow \infty$, i.e. no cut-off at the far end. Due to practical aspects (tolerances, homogeneity, etc.), an ideal phase matching ($\epsilon_{r1} \equiv \epsilon_{r2}$) is not feasible.

m) The total effect of $l$ on the coupling is not contained in $S$ alone, but in the product $l \cdot S(l \cdot f)$.

The product $l \cdot S$ is presented in figure 7 for $f = \text{constant}$. The coupling function $T$ which can be measured in a set-up, is proportional to $l$ if $l < l_C$. However, for appropriately long cables ($l > l_C$), the maximum coupling is independent of $l$ and we obtain a length independent shielding attenuation above the cut-off point $(l \cdot f)_C$. But we should remember that $(l \cdot f)_C$ as well as $A_s$ are still dependent on the set-up parameters ($\epsilon_{r1}, Z_1$).

NOTE – $S_f > S_n$ above near end cut-off, yielding a directive effect.

$(l \cdot f)_C$: cut-off point

Figure 4 – The summing function $S\{l \cdot f\}$ for near (n) and far (f) end coupling
\[ Z_T (f_1 = 10 \text{ MHz}) = 20 \text{ m\Omega/m} \]

**Figure 5a – Transfer impedance of a typical single braid screen**

**Figure 5b – Coupling transfer function for the same cable with negligible** $Z_F (Z_F \ll Z_T)$: frequency responses of figure 4 and figure 5a added on log scale

Note the cut-off effect for $f > f_C$.

Example: $\varepsilon_r 1 = 1$ (set-up), $\varepsilon_r 2 = 2.2$ (cable), $l = 1 \text{ m} \rightarrow f_{Ch} = 40 \text{ MHz}, \ f_{ Cf} = 200 \text{ MHz}$

**Figure 5 – The effect of the summing function**
Figure 6a – Calculated coupling transfer functions $T_n$ and $T_f$ for a single braided when $Z_F = 0$

- In calculations the used parameters are:
  $Z_T$ (d.c.) = 15 m$\Omega$/m and $Z_T$ (10 MHz) = 20 m$\Omega$/m increasing 20 dB/decade (see figure 5a), cable length 1 m, and velocities of the outer and inner line: $v_1 = 200$ Mm/s and $v_2 = 280$ Mm/s corresponding a velocity difference of 40%.

Figure 6b – As figure 6a but $\text{Im}(Z_T)$ is positive and $Z_F = +0.5 \cdot \text{Im}(Z_T)$ at high frequencies:

- $T_n$ is 3.5 dB higher and $T_f$ 6 dB lower than in reference figure 6a because
  $T_n \sim \frac{|Z_F + Z_T|}{|Z_F - Z_T|} = 1.5 \cdot |Z_T|$ and
  $T_f \sim \frac{|Z_F - Z_T|}{|Z_F + Z_T|} = 0.5 \cdot |Z_T|$

Figure 6c – As figure 6a but $\text{Im}(Z_T)$ is negative and $Z_F = -0.5 \cdot \text{Im}(Z_T)$ at high frequencies:

- $T_f$ is 3.5 dB higher and $T_n$ 6 dB lower than in reference figure 6a because
  $T_f \sim \frac{|Z_F - Z_T|}{|Z_F + Z_T|} = 1.5 \cdot |Z_T|$ and
  $T_n \sim \frac{|Z_F + Z_T|}{|Z_F - Z_T|} = 0.5 \cdot |Z_T|$

NOTE 1 – $T_n$ for near-end, $T_f$ for far-end and dB means that $T_{n,f}$ are calculated in dB ($20 \lg |T_{n,f}|$).

NOTE 2 – $T_n$ dB: near-end when $Z_{FT} = (1/2) \cdot Z_T$ and $T_{nzt}$ dB: near-end when $Z_F = 0$.

NOTE 3 – $T_f$ dB: far-end when $Z_{FT} = (1/2) \cdot Z_T$ and $T_{fzt}$ dB: far-end when $Z_F = 0$.

Figure 6 – The effects of the $Z_T$ and $Z_F$ to the coupling transfer functions $T_n$ and $T_f$

- In figure 6a, $Z_F = 0$.
- In figure 6b and figure 6c, $Z_F$ is significant ($Z_F = (1/2) \cdot Z_T$).
- In figure 6b $Z_T$ is positive and figure 6c negative at high frequencies.
NOTE 1 – For $l > l_c$, the maximum value of $T$ is attained, i.e. the maximum coupling (or the screening attenuation) is not dependent on $l$.

NOTE 2 – $l_{cf}$ strongly depends on $\varepsilon_{r1}$.

**Figure 7** – $l \cdot S$: the complete length dependent factor in the coupling function $T$ (see table 1)
6 Transfer impedance of a braided-wire outer conductor or screen

Typical transfer impedances of cables with braided-wire screens are shown in figure 8. The constant $Z_T$ value at the low-frequency end is equal to the DC resistance of the screen, the 20 dB/decade rise at the high-frequency end is due to the inductive coupling through the screen and the dip at the middle frequencies is caused by eddy currents or skin effect of the braid. Some braided cables may behave anomalously having less than a 20 dB/decade rise at high frequencies. By using an extrapolation of 20 dB/decade we are in most cases on the conservative side. This extrapolation can be used up to several GHz.

\[ |Z_t| \text{ Log scale} \]

where

- $f_r$: typically 1...10 MHz
- sb: single braid
- sbo: single braid optimized
- sba: single braid ‘anomalous’
- db: double braid
- ss: superscreen

Figure 8 – Transfer impedances of typical cables

An electrically short piece of braided coaxial cable (2) is considered to be placed in a triaxial arrangement as in figure 2.

It is assumed that the outer circuit (1) is the disturbing one. As stated a braided cable has a transfer impedance $Z_T$ that increases proportionally to frequency at high frequencies, because of the leakage of the magnetic field through holes in the braid.

The total flux of the magnetic field induced by the disturbing current $I_1$ is $\Phi_1$. A part of it, $\Phi'_{12}$ leaks directly through the holes and includes a disturbing voltage $U'_{2}$ in the inner circuit. However, a part $\Phi''_{12}$ of $\Phi_1$ flows in the braid and complicates the mechanism of the total magnetic leakage by the following additional phenomenon:

The braiding wires alternate between the outer and inner layer. It means that the inner and outer braid wires are likewise ingredients of both the inner (1) and outer (2) circuit of figure 9a.
Therefore it is necessary and unavoidable that $\Phi^{\prime\prime}_{12}$ is partly also in the inner circuit, figure 9b. Both the right hand (rh) and left hand (lh) lay of the braiding wires bring into the inner circuit (2) an equal disturbing voltage $U^\prime \prime_2$ induced by $\Phi^{\prime\prime}_{12} / 2$. The voltages are in parallel:

$$U^\prime \prime_{\text{rh}} = U^\prime \prime_{\text{lh}} = U^\prime \prime_2 = \frac{1}{2}j\omega\Phi^{\prime\prime}_{12}$$  (21)

This phenomenon is similar to the "magnetic part" of the coupling through a homogeneous screen.

The two induced disturbing voltages oppose each other.
Figure 10a – Complex plane, $Z_T = \text{Re} Z_T + j \text{Im} Z_T$, frequency $f$ as parameter

Figure 10b – Magnitude (amplitude), $|Z_T(f)|$

Figure 10 – Measured transfer impedance $Z_T$ (d.c. resistance $Z_T$ (d.c.) is set to the value of 10 m$\Omega$/m)
Figure 11 – Typical $Z_T$ time step response of an overbraided and underbraided single braided outer conductor of a coaxial cable

Braid optimization is based on these important physical facts. Both leakage phenomena can be described by mutual inductances:

\[ M_{12}^\prime = \frac{\Phi_{12}'}{j\omega I_1} \]  \hspace{1cm} (22)

\[ M_{12}'' = \frac{1}{2} \frac{\Phi_{12}''}{j\omega I_1} \]  \hspace{1cm} (23)

\[ \Phi_{12} = \Phi_{12}^\prime \Phi_{12}'' \]
Clearly it is possible to make braided-wire screens where either \( M'_{12} \) or \( M''_{12} \) are dominant or where they cancel each other. Therefore, underbraided, overbraided or optimized braids may be considered. Figure 10a shows measured transfer impedances in the complex plane of such screens and the main transfer impedance components of a braided screen can be observed. From the optimized case it can be concluded that at low frequencies the braid behaves approximately as a homogeneous tubular screen. The same can be concluded from figure 10b where the transfer impedance amplitudes are shown as a function of frequency, but from figure 10b it cannot be seen directly if the screen is underbraided or overbraided.

The transfer impedance of a braided-wire screen consists of the three above-mentioned main components:

(i) At low and medium frequencies the tubular screen coupling behaviour \( (Z_{Th}) \) varies with eddy currents and decreasing \( Z_T \). In [14 Vance] it is stated that a good approximation for \( Z_{Th} \) is a tubular homogeneous screen [5 Schelkunoff] with the thickness of one wire diameter and the same d.c. resistance as the braid.

(ii) The mutual inductance \( M'_{12} \) is related to direct leakage of the magnetic flux \( \Phi'_{12} \).

(iii) The mutual inductance \( M''_{12} \) (negative) is related to the magnetic flux \( \Phi''_{12} \) in the braid.

By adding these components a good approximation is obtained for the transfer impedance \( Z_T \) of a braided-wire screen

\[
Z_T = Z_{Th} + j \omega (M'_{12} - M''_{12})
\]  

(24)

and the first approximation of the equivalent circuit is shown in figure 12a.

![Figure 12b – Significant elements of circuits (1) and (2)](image)

Figure 12b – Significant elements of circuits (1) and (2)

Figure 12 – \( Z_T \) equivalent circuits of a braided-wire screen

A more complete equivalent circuit where the through capacitance \( C_T \) and surface impedances \( Z_a \) of the braided cable are incorporated is shown in figure 12b. \( L_1 \) and \( L_2 \) are the (external) inductances of the outer and inner circuit.

Many attempts have been made to calculate the transfer impedance of a braided coaxial cable. Most of the literature [15 Ikrath], [2 Kaden], [14 Vance] have concentrated on models of braided screens and calculation of direct leakage of the magnetic field induced by \( I_1 \), and of \( M'_{12} \). Satisfactory results have been achieved.
There exists very little literature [1 Fowler], [3 Tyni] on $M_{12}^\prime$ but the matter has been studied by IEC SC 46A/WG 1 and its successor TC 46/WG 5. Especially the calculation and stability of $M_{12}^\prime$ have been shown to be very problematic because of so many uncertain and unstable parameters, e.g. the resistance of the crossover points of the wires, which have an effect on the magnetic field distribution in the braid. Also the pressure of the jacket has an effect on the small space between the right hand lay and left-hand lay of the braided wires. Not to mention the number of wire ends per carrier and the braid angle and the tightness and optical coverage of the braid.

After understanding the magnetic coupling mechanisms it is not surprising that the transfer impedances of braided-wire screens vary considerably and are unstable for many braid and cable constructions whether or not they are optimized. It is also clear that a perforated tube cannot be used as a model for a braided screen.

It is clear that a loose highly optimized braid can have a very unstable $Z_T$ during bending, twisting and/or pressing. An overbraided screen with a high filling factor or optical cover normally has a (pure) negative transfer impedance at high frequencies because of a large $M_{12}^\prime$ coupling through the mutual "space" between the left and right lays of the braid in comparison with a small leakage through the braid $M_{12}^\prime$. Pressure on the jacket would improve the screening performance by diminishing the mutual "space" and decrease the $Z_T$.

The manufacture of a good stable optimized cable requires the control of braid parameters such as:

- braid angle, tension (and lubricant) of the strands;
- number of strand in a spindle;
- wire diameter;
- plating:
- pressure on the braid;
  - in manufacturing;
  - of the jacket.

IEC TC 46/WG 5, Screening effectiveness, is studying the impact of these parameters on an optimized braid when preparing a guide for braided optimization based on theory and practice.

A guide on screening optimization of braids will help the IEC family to talk the same language when setting limits for electromagnetic screening parameters ($Z_T$, $Z_F$, $a_e$) of braided cables.

7 Test possibilities

A number of test procedures are used to test cables for their screening properties, some of which will be found in IEC standards. Each procedure has benefits for some users which for historical reasons may not be widely appreciated. Table 2 summarizes the test procedures available, some of which will be discussed here, with special reference to their applicability to cables, cable assemblies and connectors.

7.1 Measuring the transfer impedance of coaxial cables

All tests listed in table 2 can be used on coaxial cables, but if a single test is needed to cover frequencies above and below 100 MHz, tests 1, 4, 7, 9 and 10 can be dismissed. Of the others, those with 's' under 'grouping' (column 3) have better intrinsic isolation between measuring and injection circuits, while in those with 'o' under grouping the injection circuit is unscreened. The difference is the line interchange referred to in section 4.4 above. One benefit of an unscreened injection line is that better access may be obtained for inspection of the cable under test, which may be useful if the sample is in any way flawed. The two test methods with unscreened injection lines are 3 and 8. The latter, with its wide frequency coverage is recommended for future testing.
7.2 Measuring the transfer impedance of cable assemblies

Even with a restricted frequency range, many of the tests listed in table 2 are not suited to tests on cable assemblies. Tests 1, 4, and 6 are unsuitable because an electrically short sample may be needed to achieve the upper frequencies, while test 10 is still limited to frequencies above 100 MHz. Tests with screened injection wires (2 and 5) are difficult to set up due to the varying cross section of the assembly, a difficulty which also applies to test 3. Such objections leave tests 7, 8 and 9. To set against its low (effective) upper frequency limit, with test 7 it is easy to distinguish between connector and cable contributions, so it is ideal in a diagnostic role. Test 9 works only above 30 MHz, which may be restrictive. Test 8 will require several measurements on each sample, as it is unreasonable to assume that a cable assembly has circular symmetry.

It is only fair to state that in any frequency domain test on cable assemblies where signal phase is not recorded, a test is only valid if the sample length is not varied (tests carried out on a sample of one length, cannot be used to assess a sample of another length – whether it be longer or shorter). Of the transfer impedance tests being discussed, only test 7 can be used in this way.

Multi-conductor cable assemblies are more complex, because the 'core' cannot be considered to be coaxial. A test for such cable assemblies has not yet been addressed.

7.3 Measuring the transfer impedance of connectors

In principle, all the tests in table 2 can be used on coaxial connectors.

As with tests on cable assemblies, there is much benefit to be gained from using a test with an unscreened injection circuit, though other tests will remain in the standard, because they have become accepted. If it is possible to distinguish the screening of a connector from that of the attached cable, this will considerably ease the test procedure.

Multi-pin connectors are far more numerous and varied than coaxial connectors. However, non-circular connectors cannot be tested by the means implied by the test procedures of table 2, though by suitable variation test 7 and test 10 would become appropriate. This problem is under study.

NOTE – These methods give only an outline for measurement of symmetrical multicore cables, multipin connectors and cable assemblies made with these components.

The problems to address come from:

a) the fact that a connector is electrically short, while the parameters of a cable are distributed, and it may be electrically long;

b) multi-core cables rarely have circular symmetry. This applies both physically and to the signal paths on their conductors;

c) most multi-pin connectors have no circular symmetry; nor are they equally spaced from other conductors, which might couple to them;

d) economics will dictate that a cable assembly test should apply to other assemblies using the same components, even though of differing overall length.

\[
M_{12} = \frac{\Phi'_{12}}{j\omega L_1} \quad \text{and} \quad M''_{12} = \frac{1}{2} \frac{\Phi''_{12}}{j\omega L_1}
\]
The near end transfer function is given by:

\[ T_{n,f} = T_{n} \]

- \( U'_{2} \): The disturbing voltage induced by \( \Phi'_{12} \)
- \( U''_{rh} \): The disturbing voltage induced by \( \frac{1}{2} \Phi''_{12} \) of the right hand lay contribution
- \( U''_{lh} \): The disturbing voltage induced by \( \frac{1}{2} \Phi''_{12} \) of the left hand lay contribution
- \( U''_{2} \): Is equal to \( U''_{rh} \) and \( U''_{lh} \) (= the disturbing voltage induced by \( \frac{1}{2} \Phi''_{12} \))
- \( v \): Phase velocity
- \( v_1 \): Phase velocity of the "primary" system (feeding system)
- \( v_2 \): Phase velocity of the "secondary" system (measuring system)
- \( v_{r1} \): Relative phase velocity of the "primary" system (feeding system)
- \( v_{r2} \): Relative phase velocity of the "secondary" system (measuring system)
- \( Z_1 \): Characteristic impedance of the "primary" system (feeding system or line (1))
- \( Z_2 \): Characteristic impedance of the cable under test (CUT) (measuring system or line (2))
- \( Z_{1f} \): Terminating impedance of the line (1) in the far end
- \( Z_{2n} \): Terminating impedance of the line (2) in the near end
- \( Z_{2f} \): Terminating impedance of the line (2) in the far end (in a matched set-up \( Z_{1f} = Z_1 \) and \( Z_{2n} = Z_{2f} = Z_2 \))

\[ Z_{12} = \sqrt{Z_1 Z_2} \]

- \( Z_a \): Surface impedance of the braided cable
- \( Z_F \): Capacitive coupling impedance per unit length
- \( Z_t \): Capacitive coupling impedance
- \( Z_T \): Surface transfer impedance per unit length
- \( Z_{Th} \): Transfer impedance of a tubular homogeneous screen per unit length
- \( Z_{ten} \): Surface transfer impedance
- \( Z_{Ten} \): Effective transfer impedance (= \( |Z_F + Z_T| \)) per unit length in the near end
- \( Z_{TEf} \): Effective transfer impedance (= \( |Z_F - Z_T| \)) per unit length in the far end
- \( Z_{Ten,f} \): Effective transfer impedance (= \( |Z_F \pm Z_T| \)) per unit length in the near end or in the far end
- \( Z_{TE} \): Effective transfer impedance (= \( \max \{|Z_{Ten}, Z_{TEf}|\} \)) per unit length
- \( Z_{te} \): Effective transfer impedance (= \( \max \{|Z_t, Z_i|\} \))
- \( Z_{ten} \): Normalized effective transfer impedance of a cable \( (Z_1 = 150 \, \Omega \) and \( |v_1 - v_2| / v_2 \leq 10\% \) velocity difference in relation to velocity of CUT)

We at the IEC want to know how our standards are used once they are published. The answers to this survey will help us to improve IEC standards and standard related information to meet your future needs.

Would you please take a minute to answer the survey on the other side and mail or fax to:

Customer Service Centre (CSC)
International Electrotechnical Commission
3, rue de Varembé
Case postale 131
1211 Geneva 20
Switzerland

or

Fax to: CSC at +41 22 919 03 00

Thank you for your contribution to the standards making process.
1. No. of IEC standard: .......................................................

2. Tell us why you have the standard. (check as many as apply). I am:
   - the buyer
   - the user
   - a librarian
   - a researcher
   - an engineer
   - a safety expert
   - involved in testing
   - with a government agency
   - in industry
   - other........................................

3. This standard was purchased from?
   .......................................................

4. This standard will be used (check as many as apply):
   - for reference
   - in a standards library
   - to develop a product
   - to write specifications
   - to use in a tender
   - for educational purposes
   - for a lawsuit
   - for quality assessment
   - for certification
   - for general information
   - for design purposes
   - for testing
   - other........................................

5. This standard will be used in conjunction with (check as many as apply):
   - IEC
   - ISO
   - corporate
   - other (published by ...............)
   - other (published by ...............)
   - other (published by ...............)

6. This standard meets my needs (check one)
   - not at all
   - almost
   - fairly well
   - exactly

7. Please rate the standard in the following areas as (1) bad, (2) below average, (3) average, (4) above average, (5) exceptional, (6) not applicable:
   - clearly written
   - logically arranged
   - information given by tables
   - illustrations
   - technical information

8. I would like to know how I can legally reproduce this standard for:
   - internal use
   - sales information
   - product demonstration
   - other.................................

9. In what medium of standard does your organization maintain most of its standards (check one):
   - paper
   - microfilm/microfiche
   - mag tapes
   - CD-ROM
   - floppy disk
   - on line

9A. If your organization currently maintains part or all of its standards collection in electronic media, please indicate the format(s):
   - raster image
   - full text

10. In what medium does your organization intend to maintain its standards collection in the future (check all that apply):
    - paper
    - microfilm/microfiche
    - mag tape
    - CD-ROM
    - floppy disk
    - on line

10A. For electronic media which format will be chosen (check one)
    - raster image
    - full text

11. My organization is in the following sector (e.g. engineering, manufacturing) .................................................................

12. Does your organization have a standards library:
    - yes
    - no

13. If you said yes to 12 then how many volumes:
    ....................................................

14. Which standards organizations published the standards in your library (e.g. ISO, DIN, ANSI, BSI, etc.):
    ....................................................

15. My organization supports the standards-making process (check as many as apply):
    - buying standards
    - using standards
    - membership in standards organization
    - serving on standards development committee
    - other......................................

16. My organization uses (check one)
    - French text only
    - English text only
    - Both English/French text
